
General Information

Detailed information about the lecture, tutorials and homework assignments can be found on the lecture website¹. Solutions have to be submitted to Moodle². Upload your solutions as a single file named 'hw06.ml' to moodle. Since submissions are tested automatically, solutions that do not compile or do not terminate within a given time frame cannot be graded and thus result in 0 Points. If you do not manage to get all your stuff compiling and/or terminating, comment the corresponding parts of the file! Use Piazza³ to ask questions and discuss with your fellow students.

Functional Programming

Since this is a course about functional programming, we restrict ourselves to the functional features of OCaml. In other words: The imperative and object oriented subset of OCaml is not used. **Assignment 6.5 (H) Peano Arithmetic** [3 Points]

The natural numbers can be defined recursively as follows:

- 0 is a natural number.
- if n is a natural number, then so is the successor of n

We can easily represent this in OCaml using corresponding constructors: Implement the following functions for natural numbers:

1. converts an integer to natural.
2. converts a natural to integer.
3. adds two natural numbers.
4. multiplies two natural numbers.
5. a call `exp` computes a^b .
6. a call `leq` computes $a \leq b$.

You are **not** allowed to use the first two functions to implement the rest!

Assignment 6.6 (H) Quadtrees

[6 Points]

The quadtree data structure stores points by recursively partitioning a 2-dimensional region.

Let $Rect(x_1, y_1, x_2, y_2)$ denote the rectangular region with lower left corner (x_1, y_1) and upper right corner (x_2, y_2) . We define that all points (x, y) with $x_1 \leq x < x_2$ and $y_1 \leq y < y_2$ belong to this region. Every internal node represents a rectangular region $Rect(x_1, y_1, x_2, y_2)$ and has exactly four children, which represent the equally sized subregions $Rect(x_1, y_1, x_c, y_c)$, $Rect(x_1, y_c, x_c, y_2)$, $Rect(x_c, y_1, x_2, y_c)$ and $Rect(x_c, y_c, x_2, y_2)$, respectively, where $(x_c, y_c) = (\frac{x_2+x_1}{2}, \frac{y_2+y_1}{2})$ is the nodes center point. Leafs are either empty or contain a single point.

At all times, every subtree rooted at node N has the minimal height required to store all points that are inside the region corresponding to N . Every point (x, y) is stored at most once, so if the same point is inserted a second time, the tree is unchanged. The following figure shows a quadtree of size 512x512 that stores 100 points along the sine wave:

We represent a quadtree node by the following sum type: and the entire quadtree with region $Rect(0,0,width,height)$ is then represented by the type: Note, that we do not store the region inside the individual nodes, but just in the tree itself, so node regions must be computed during tree traversal.

Implement the function `insert` that inserts a point into the tree.

Hint: You may assume that region sizes are always a power of 2 and that `insert` is only called for points (x,y) that go into the tree's region ($0 \leq x < width \wedge 0 \leq y < height$)

Hint: The function `save_svg` is provided to save an svg-image of your tree.

Assignment 6.7 (H) Expression Evaluation

[4 Points]

We define expressions over rationals using these OCaml types: Implement a function `eval` that evaluates the given expression. The resulting fraction need not be simplified, so `1/2`, `2/4`, `3/6`, ... are all accepted. Example: `eval (1/2 + 1/3)` evaluates to `5/6` (or `10/12`).

Assignment 6.8 (H) Crawling on Trees

[7 Points]

Once again, consider binary trees, which we define as: In this assignment you are supposed to implement a crawler that walks along binary trees and performs different operations. At any time, the crawler “sits” on a particular node of the tree (this includes the -leaf). In the following we refer to this node as the *current node*. Furthermore, the crawler uses a stack to store trees. Initially, the crawler is positioned at the input tree’s root and is then instructed using the commands with the following meaning:

- moves the crawler to the current node’s left child.
- moves the crawler to the current node’s right child.
- moves the crawler up to the current node’s parent node.
- replaces the current node (including all children) with a new node with value .
- removes the current node (including all children) leaving behind an -leaf.
- pushes the subtree rooted at the current node onto the stack. The tree stays unchanged.
- replaces the subtree rooted at the current node with the topmost tree of the stack. The tree is then popped from the stack.

Implement a function `crawler` that executes a list of crawler commands on the given tree. You may assume that the list of commands is always valid, so there is no `error` when the crawler is already at a leaf, no `error` when it is on the root and no `error` when the stack is empty.

Hint: The tricky part is to get the `replace` command right. If you do not manage to implement this correctly, leave it out and you will still get some points for the rest.

Hint: The function `tree2dot` is provided, that can be used to `dot`⁴-export your tree.
